## CONVERSION FACTORS

---

Metric units are used in this report. For readers who prefer inch-pound units, the conversion factors for the terms used in this report are listed below.

| <u>Multiply</u>               | <u>By</u> | <u>To obtain</u> |
|-------------------------------|-----------|------------------|
| cm (centimeter)               | 0.3937    | inch             |
| km (kilometer)                | 0.6214    | mile             |
| m (meter)                     | 3.281     | foot             |
| m <sup>2</sup> (square meter) | 10.76     | square foot      |
| mm (millimeter)               | 0.03937   | inch             |

## TRADE NAMES

The use of brand or trade names in this report is for identification purposes and does not imply endorsement by the U.S. Geological Survey.

PHYSICAL AND CHEMICAL PROPERTIES OF SAN FRANCISCO BAY, CALIFORNIA, 1980

---

By Allan Y. Ota, Laurence E. Schemel, and Stephen W. Hager

---

ABSTRACT

The U.S. Geological Survey conducted hydrologic investigations in both the deep-water channels and the shallow-water regions of the San Francisco Bay estuarine system during 1980. Cruises were conducted regularly, usually at two-week intervals. Physical and chemical properties of the water column were measured at regularly-occupied stations. Measurements of physical and chemical properties presented in this report include temperature, salinity, suspended particulate matter, turbidity, extinction coefficient, partial pressure of CO<sub>2</sub>, partial pressure of oxygen, dissolved organic carbon, particulate organic carbon, discrete chlorophyll-a, fluorescence of photosynthetic pigments, dissolved silica, dissolved phosphate, nitrate plus nitrite, nitrite, ammonium, dissolved inorganic nitrogen, dissolved nitrogen, dissolved phosphorus, total nitrogen, and total phosphorus. Analytical methods are described.

## INTRODUCTION

The U.S. Geological Survey conducted hydrologic investigations in both the deep-water channels and the shallow-water embayments of the San Francisco Bay estuarine system during 1980. Sampling cruises were scheduled regularly during the year, usually at two-week intervals (table 1), during each of which a suite of physical, chemical, and biological variables was measured (table 2). This report presents the physical and chemical measurements made at regularly-occupied locations in the estuary (tables 3a and 3b) during these sampling cruises. Similar data collected at additional locations and times during 1980 have been reported by Dedini and others (1981) and Schemel (1984 a,b). The biological data are described in the following reports: Ambler and others (1985) for zooplankton, Wong and Cloern (1982) for phytoplankton species and abundances, and Cole and others (1986) for phytoplankton productivity.

## ACKNOWLEDGMENTS

We thank the captain and crew of the R/V Polaris and the many scientists and technicians who were responsible for the quality of the data collected during this investigation. We thank Brian Cole and Andrea Alpine for the chlorophyll-a data, and thank Dana Harmon and Ray Herndon for initial entry and editing of the data.

## METHODS

Two vessels were used in this study. The R/V Polaris occupied deep-water stations along the main channel, and a shallow-draft vessel, the R/V Estero, occupied stations in the shallow-water areas of the bay. Transect lines showing the location of sample stations which correspond to locations listed in tables 3a and 3b are shown in figures 1a and 1b.

Physical properties and concentrations of dissolved and particulate substances in water obtained through intakes near the bow of each vessel were measured continuously, and discrete samples for additional measurements and for calibration of continuously-measuring instruments were collected at specific locations. The bow intake was about 2 meters below the surface on the R/V Polaris, and about 1 meter below the surface on the R/V Estero. A submersible pump aboard the Polaris was used to obtain water at deeper depths. Details of the pumping systems and the continuously-measuring instruments on both vessels are documented by Schemel and Dedini (1979) and Dedini and Schemel (1980). Continuous measurements on the R/V Polaris were temperature at the bow or submersible pump intakes, salinity, turbidity, pH and the sample temperature in the pH flow cell, the partial pressure of carbon dioxide, the partial pressure of oxygen, and chlorophyll a fluorescence. A reading was made at each station mark for each continuous measurement. Discrete samples were collected for measurements of dissolved nutrients, total nutrients, chlorophyll-a, dissolved and particulate organic carbon, and suspended particulate matter. Extinction coefficients were measured when the vessel was anchored on station. Comparable continuous and discrete sample measurements were made on the R/V Estero. A major difference was that concentrations of dissolved inorganic nutrients were continuously measured on the R/V Estero.

## Continuous Measurements

Salinity was measured continuously with a flow-sample electrodeless induction salinometer. The calibration procedure is described by Dedini and others (1981); continuously measured salinities agreed with those measured in the laboratory usually within +/- 0.05 salinity units.

All temperatures were measured by linearized thermistor probes inserted into the sample stream. The probes were routinely calibrated at ice point and near 20°C. Temperature measurements were accurate to approximately +/- 0.1°C.

The abundance of light-scattering and -absorbing constituents in the water, referred to here as turbidity, was measured by a Turner Designs Model 10 fluorometer equipped with a nephelometry flow cell (R/V Polaris; Schemel, 1975) and a Turner Designs Model 40 nephelometer (R/V Esterio). Instrument readings were related to concentrations of suspended particulate matter (see below) by linear regression. Turbidity data are expressed as the predicted concentrations of suspended particulate matter, but are unitless in the data tables to differentiate these semi-quantitative turbidity values from measured concentrations.

The pH was determined electrometrically. Electrodes were calibrated in buffer solutions of pH 7.413 and 4.008 at 25°C (Bates, 1954). A temperature correction was applied to the data using an average slope of 0.010 pH/°C (Harvey, 1957).

The partial pressure of carbon dioxide ( $pCO_2$ ) in the water was estimated by measuring the  $CO_2$  content of air equilibrated with the sample stream. The carbon dioxide concentration was determined by an infrared analyzer (Gordon and Park, 1972, and Broecker and Takahashi, 1966), and is expressed as ppt (by volume) in dry air. These measurements typically agreed within +/- 5 percent of those calculated from discrete pH and alkalinity measurements.

Dissolved oxygen was measured with a membrane-covered polarographic electrode (Yellow Springs Instrument Co.). Thermistors within the electrode were rewired to compensate for the change in the permeability of the membrane with respect to temperature, but not for the relationship between temperature and the solubility of oxygen in water. Therefore, the electrode responded to the partial pressure of oxygen. Calibrations were performed in air, and the data are referenced to the partial pressure of oxygen in air (100 percent). These results are considered semiquantitative.

A Turner Designs Model 10 fluorometer measured fluorescence associated with chlorophyll-a of phytoplankton, other chlorophylls, and their degradation products (Lorenzen, 1966). Data are expressed in relative units, and are considered semi-quantitative.

## Discrete Sample Measurements

Particulate and dissolved organic carbon was measured by the method of Menzel and Vaccaro (1964). Particles were collected on precombusted glass fiber filters. Organic carbon was wet oxidized using potassium persulfate in sealed glass ampules. The  $CO_2$  content of each ampule was related to the carbon content on the filter by a standard curve prepared by oxidation of standard sucrose solutions. Additional details of the method for particulate organic carbon are given by Schemel and Dedini (1979). Estimated precisions for dissolved and particulate organic carbon measurements were +/- 0.2 mg/L and +/- 0.1 mg/L, respectively (Schemel, 1984b).

A Secchi disk was used to measure the attenuation of light at fixed stations. The extinction coefficient (EXT COEF) was calculated as 1.5/d where d is the Secchi depth in meters (Perkins, 1975).

Chlorophyll a was measured by the method described by Strickland and Parsons (1972). Calculations were based on the trichromatic equation recommended by SCOR-UNESCO Working Group 17 (1966). Precision of the analysis was +/- 10 percent, as estimated from replicates.

Concentrations of suspended particulate matter were determined gravimetrically. An aliquot of sample water was vacuum filtered through a preweighed 47 mm-diameter, 0.45 um pore-size silver filter. The filter was air dried for a minimum of four weeks, then weighed. After additional drying time, the filter was reweighed. Corrections were made for the weight of salt on the filter, on the basis of experiments where filters were rinsed with bicarbonate water and on other experiments where small quantities of previously filtered saltwater were filtered. Mean and median deviations were typically 1.4 and 0.9 mg/L, respectively (Hager and Harmon, 1984).

#### Nutrient Measurements

Concentrations of nutrients were measured using a Technicon AutoAnalyzer II system. For the continuous measurements on the R/V Ester, the pumped sample stream was filtered through a 0.45 um membrane filter, with vacuum supplied by a variable speed tubing pump. The filtrate was delivered to a 3 mL reservoir from which the AutoAnalyzer continuously drew its sample. Because difficulties with the continuous filtration system lead to excessive baseline drift, and because of other factors associated with operations on a small vessel underway, continuous nutrient measurements are believed to be less accurate than those measured from discrete samples.

Discrete samples for dissolved inorganic nutrient analysis were filtered through 47mm diameter, 0.4 um pore-sized Nuclepore polycarbonate membrane filters under vacuum (less than 17 kPa). Filtered samples were stored in 30 mL amber Nalgene linear-polyethylene bottles that had been preconditioned by soaking in a 2.5 meq/L solution of sodium bicarbonate. Samples were vigorously shaken before analysis.

At some stations, samples were collected for total nitrogen (TN), total phosphorus (TP), dissolved nitrogen (DN), and dissolved phosphorus (DP). Total (unfiltered) and dissolved (gravity-filtered through a glass fiber filter) samples were digested using hydrogen peroxide and ultraviolet light prior to analysis. The method is described for nitrogen by Hager and Harmon (1984). After digestion, samples were analyzed for ammonium, nitrate plus nitrite, and dissolved reactive phosphate (subsequently referred to as phosphate) by the methods given below. Because the hydrogen peroxide and ultraviolet light digestion does not mineralize all forms of nitrogen, and because the "total" samples were membrane filtered after digestion prior to analysis removing particle-adsorbed phosphorus, TN and TP both could be underestimates of the true total amounts of these elements in the sample.

Concentrations of ammonium, nitrate, nitrite, dissolved reactive phosphate, and dissolved silica were measured simultaneously on a Technicon AutoAnalyzer II system. Analyzer responses were linear over the ranges of concentrations encountered in this study. Standard curves were based on upscale standards and blanks that were analyzed at two- to four-hour intervals. Standards were prepared in artificial river water (1.0 meq/L solution of sodium bicarbonate) and artificial seawater (Strickland and Parsons (1972)). The analyzer was maintained at constant temperature by circulating 37°C water through tubes inserted through the centers of the glass mixing coils on each manifold.

The ammonium method was an automated version of the phenol-hypochlorite method of Solorzano (1969), with color development at 37°C as recommended by Berg and Abdullah (1977). This temperature and the increased reaction time resulting from the addition of ten-turn coils in place of five-turn coils and two additional twenty-turn coils before the heating bath gave maximum color development and low blanks. Typical precision was +/- 0.2 umol/L.

The nitrate + nitrite method was the Technicon (1973) method number AII-100-70W with one twenty-turn coil added to increase reaction time for better color stability. 0.121 g of copper sulfate was added per 20 liters of ammonium chloride solution, as suggested by Connors and Beland (1976). The pH of this reagent was not adjusted. Typical precision was +/- 0.1 umol/L. Nitrate can be calculated by subtracting the corresponding concentration of nitrite from the results of this analysis.

The nitrite method was an adaptation of the Technicon (1973) method number AII-100-70W with the cadmium column removed. To fit all five analyses for nutrients on a single proportioning pump, the sample-ammonium chloride mixture was drawn from the debubbler which preceded the cadmium column in the nitrate + nitrite analysis. Typical precision was +/- 0.05 umol/L.

The dissolved silica method was a modification of the Technicon (1976) method number AII-105-71W. The acid-molybdate reagent was diluted and its flow rate increased, keeping the acid- and molybdate-to-sample ratios unchanged. Additional mixing coils were added to give more complete color development. Typical precision was +/- 1 umol/L.

The phosphate method was a modification of that of Atlas and others (1971), using ascorbic acid (70 g plus 50 mL acetone per liter of solution) as a reductant. This modification allowed analysis of samples predigested with hydrogen peroxide in ultraviolet light, as described below. To increase reaction time for maximum color development, ten-turn coils replaced the five-turn coils and a twenty-turn coil replaced the ten-turn coil in the manifold design. Typical precision was +/- 0.05 umol/L.

## RESULTS

The body of data contained in this report characterizes hydrologic conditions in San Francisco Bay during a year with an average rate of freshwater inflow to the estuary. These data are also the product of the first effort on the part of the U.S. Geological Survey to collect detailed measurements in the shallow water areas that compose most of the major sub-embayments. To obtain an adequate level of detail, continuous measurements were employed on the R/V Estero, when possible. In the case of nutrients, concentrations were measured in the flow from a continuous filtration system and in discrete samples that were collected simultaneously. We provide here details of our quality control on the continuous measurements as provided by comparisons with measurements of discrete samples.

Concentrations of nutrients in discrete samples were determined by identical methods for both the R/V Polaris and R/V Estero samples. The continuous filtration system on the R/V Estero, however, constituted a significant change in methodology that might have been more subject to error. Thus, we make the assumption that measurements of discrete samples are representative of the true values in our analysis of the data. Consequently, in linear regression analysis of the data sets we treated the continuous values as functions of the discrete-sample values.

Approximately 250 discrete samples were collected over the year on the R/V Estero while nutrients were measured continuously. Approximately 20 percent of these samples were collected in the South Bay (figure 1a). In some cases the ranges of concentrations in the South Bay were different from those in the reach of the bay to the north (northern reach), thus affecting the distributions of concentration values in the analyses below.

Concentrations of dissolved silica (discrete-sample) ranged from 3.8 to 310  $\mu\text{M}$  in the northern reach of the bay, whereas the range in the southern reach was limited to 63 to 150  $\mu\text{M}$  (figure 2a). Differences in concentrations (expressed here and below as discrete values minus continuous values) were generally small, with more than 50 percent of the differences less than 5  $\mu\text{M}$ . Linear regression analysis yielded a coefficient of determination ( $r^2$ ) of 0.99, an intercept of 3.3  $\mu\text{M}$ , and a slope of 0.95.

Concentrations of phosphate (discrete-sample) ranged from 1.3 to 4.4  $\mu\text{M}$  in the northern reach, which was narrow in comparison with that of 2.2 to 19.0  $\mu\text{M}$  in the southern reach (figure 2b). Differences in concentrations were generally small, with more than 50 percent of the differences less than 0.2  $\mu\text{M}$ . Five samples from the southern reach exhibited large differences, with continuous values between 2 and 8  $\mu\text{M}$  higher than discrete-sample values. These values were included in the linear regression analysis, which yielded a coefficient of determination of 0.90. The intercept and slope values were 0.29  $\mu\text{M}$  and 0.99, respectively.

Concentrations of nitrate plus nitrite (discrete-sample) ranged from near zero to 53  $\mu\text{M}$  in the northern reach, and from 2.3 to 64  $\mu\text{M}$  in the southern reach (figure 3a). Differences in concentrations were generally small, with more than 50 percent of the differences less than 1.0  $\mu\text{M}$ . Nine samples showed large differences where discrete-sample values exceeded continuous values by 6  $\mu\text{M}$  or more. In spite of these outliers, linear regression analysis of all the data yielded a coefficient of determination of 0.98. The intercept and slope values were 1.4  $\mu\text{M}$  and 0.90, respectively. The low slope value was in part an effect of the outliers, all of which exceeded 50  $\mu\text{M}$  in concentration.

Concentrations of nitrite (discrete-sample) were low in both reaches, exhibiting a range from nearly zero to approximately 2.3  $\mu\text{M}$  (figure 3b). Nitrite is an intermediate product in the nitrification of ammonium to nitrite, a factor that could be responsible for differences between continuous values and values from discrete samples, which were stored for a period of time before analysis. Differences in concentrations were generally small, with more than 50 percent of the differences less than 0.2  $\mu\text{M}$ . However, many samples with higher than average concentrations showed large differences. Continuous values from two samples from the northern reach exceeded the discrete-sample values by 1.96 and 2.05  $\mu\text{M}$ , and four discrete-sample values from the southern reach exceeded the continuous values by 0.9  $\mu\text{M}$  or more. Consequently, linear regression analysis of all the data yielded a coefficient of determination of only 0.55 and a very low value for slope, 0.74.

Concentrations of ammonium (discrete-sample) ranged from near zero to 14.2  $\mu\text{M}$  in the northern reach, and from near zero to 8.3  $\mu\text{M}$  in the southern reach (figure 4). Over 50 percent of the differences between values were less than 0.3  $\mu\text{M}$ . Linear regression analysis yielded a coefficient of determination of 0.87, an intercept of 0.12  $\mu\text{M}$ , and a slope of 1.0.

Numerical values for all measurements are listed in tables A and B in the appendix.

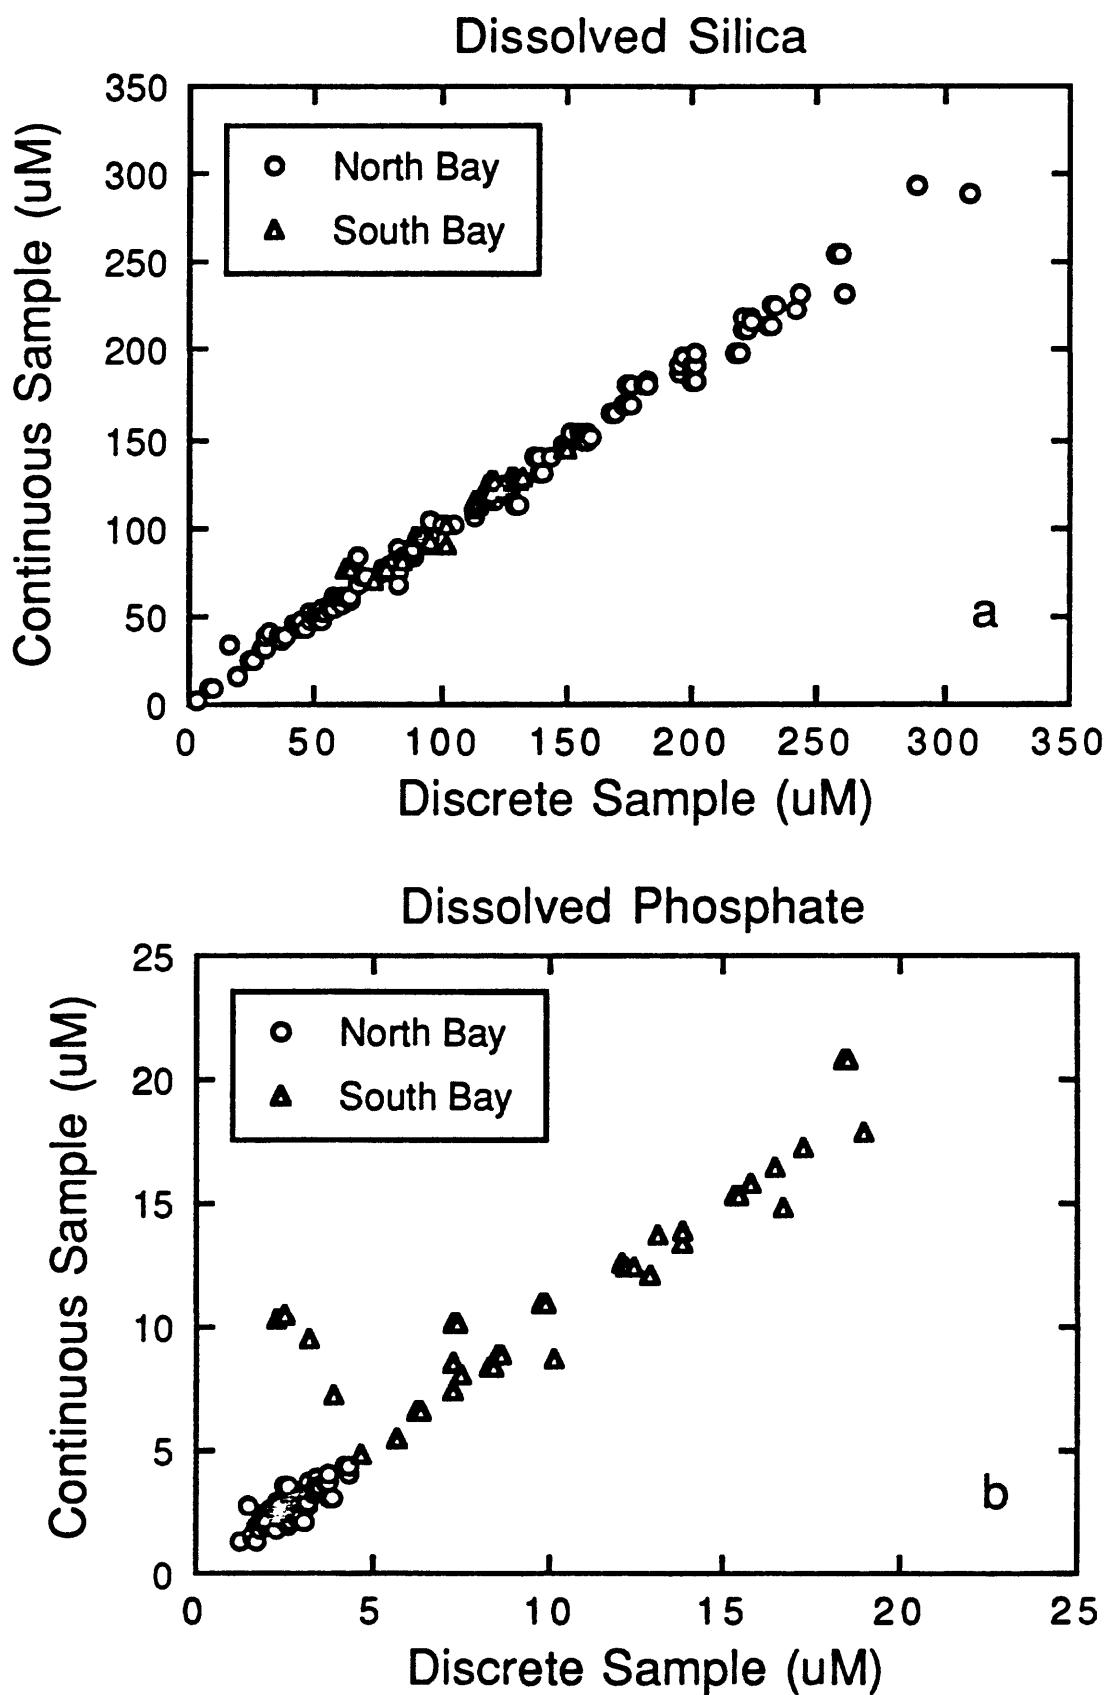

Figure 2. Comparison of continuous versus discrete nutrient measurements: dissolved silica (a) and dissolved phosphate (b).

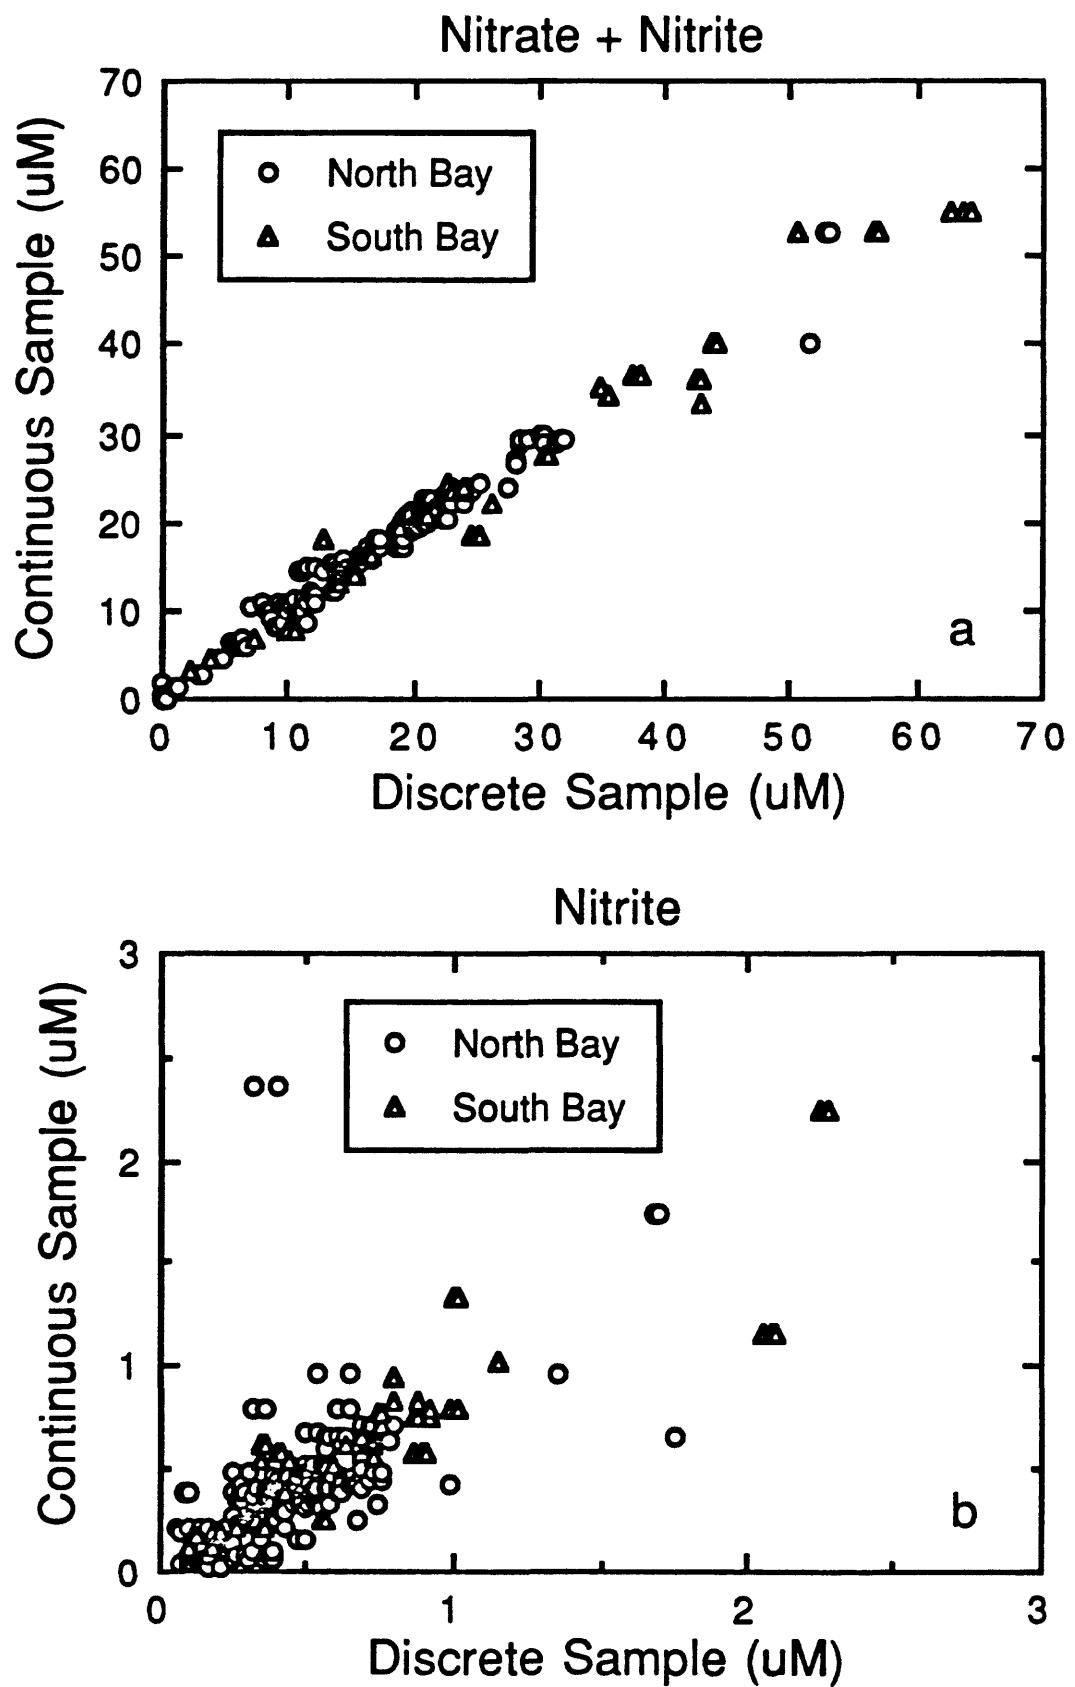

Figure 3. Comparison of continuous versus discrete nutrient measurements: nitrate + nitrite (a) and nitrite (b).

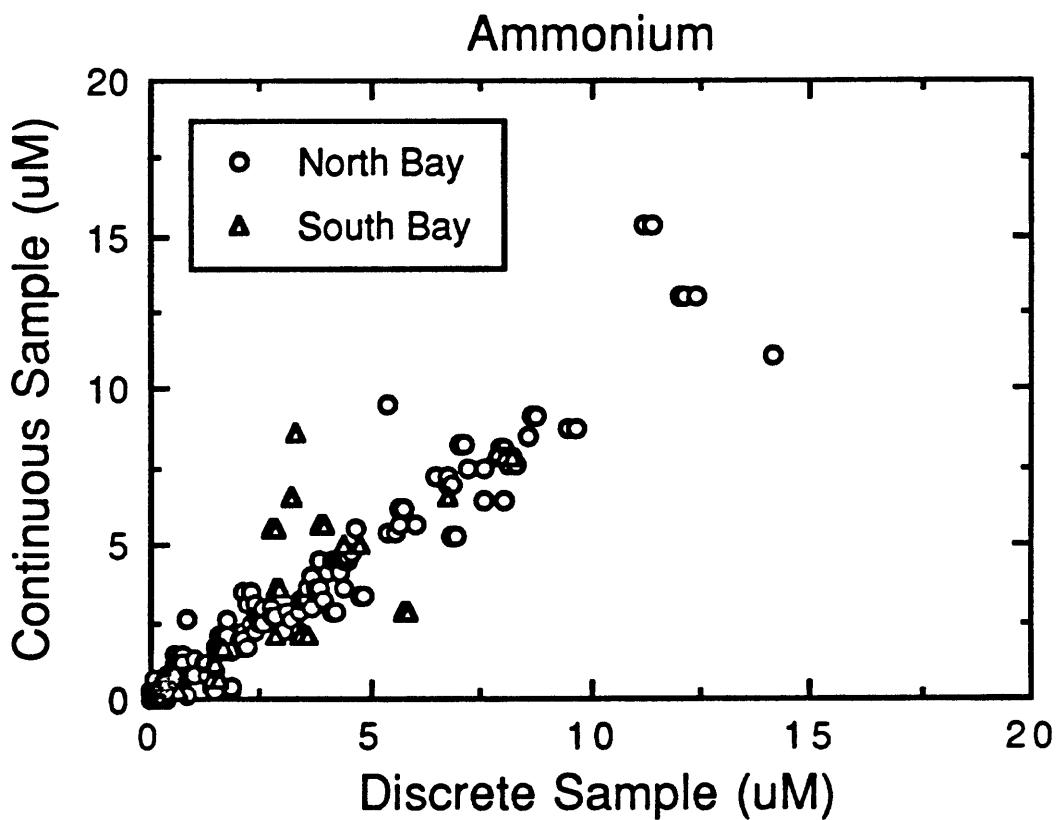

Figure 4. Comparison of continuous versus discrete nutrient measurements: ammonium.
